

1. The average BAC of eight male subjects was measured after consumption of 15 mL of ethanol. The resulting data were modeled by the concentration function

$$C(t) = 0.0225te^{-0.0467t}$$

where t is measured in minutes after consumption and C is measured in mg/mL.

- (a) How rapidly was BAC increasing after 10 minutes?

- (b) How rapidly was BAC decreasing half an hour later?

2. The brightness of a star in units of m_V (apparent magnitude) is given by

$$B(t) = 4.0 + 0.35 \sin\left(\frac{2\pi t}{5.4}\right)$$

where t is measured in days. Find the rate of change of brightness after one day and interpret your answer. Include units.

3. Compute $\lim_{t \rightarrow \infty} h(t)$ and interpret what this means.

4. Find all the locations where the tangent to the curve $y = 2 \cos(x) + \cos^2(x)$ is horizontal.

5. Compute $f'(t)$ if $f(t) = e^{at} \sin(bt)$, where a and b are constants.

6. Find y'' if $y = \cos(\sin(3x))$.
